Artificial intelligence jump starts clinical trial for rare genetic disease

by Bob Shepard

May 07, 2020 | Print | Email

It was a pretty simple e-mail. Just a couple of lines. "It looks like low-dose ketamine is an up-regulator for ADNP. Do you think this makes sense for ADNP patients?"

Matt Might sent that e-mail to Matt Davis on Feb. 18, 2019. Might is the director of the Hugh Kaul Precision Medicine Institute at the University of Alabama at Birmingham School of Medicine. Davis is chief resident in the Department of Neurosurgery at UAB and the father of Benjamin, a child with a developmental delay caused by a variant in the ADNP gene.

And that e-mail was the first step toward a just-launched clinical trial that may make a world of difference for children like Benjamin.

Low-Dose Ketamine in ADNP Syndrome

- Ketamine is an N-methyl-D-aspartate (NMDA) antagonist that enhances excitatory (glutamatergic) nerve cell functioning by blocking inhibitory nerve cells (GABAergic interneurons)
- Ketamine also increases nerve cell growth factors (neurotrophins) to influence synaptic plasticity.
- While high-dose ketamine has toxic effects in animal models, these effects can be prevented by pre-treatment with low-dose ketamine.

Specific Aims

- **Aim 1.** Evaluate safety and tolerability of low dose ketamine in children with ADNP syndrome
- **Aim 2.** Evaluate efficacy targeting measures of aberrant behavior, sensory reactivity, sleep, language, and adaptive functioning
- **Aim 3.** Explore the feasibility of electrophysiological markers and computerized eye tracking
- **Aim 4.** Explore the feasibility of blood-based biological markers using RNA sequencing to measure ADNP expression and DNA methylation analysis

Participant Characteristics

Demographic Categories	Proportion or Mean (SD)	Range
Total Sample	10	
Sex		
Female	3/10	
Male	7/10	
Age: years	9.50 (2.30)	6.35–12.85
Developmental Quotient		
Verbal	26.71 (15.33)	5.65–52.48
Nonverbal	31.28 (16.13)	8.87–58.42
Full Scale	28.81 (15.42)	7.26–54.5
ASD	4/10	
ADHD	7/10	
Genetic Mutation		
Frameshift	6/10	
Nonsense	4/10	
Race and Ethnicity		
Hispanic/Latino	2/10	
White	8/10	

Results: Safety

Adverse event type	N (%)
Elated / silly	5 (50)
Aggression	4 (40)
Fatigue	4 (40)
Decreased appetite	3 (30)
Anxiety	3 (30)
Restless	2 (20)
Increased fluid intake	2 (20)
Nausea/vomiting	2 (20)
Moody / irritable	2 (20)
Self-injury	1 (10)
Gagging / reflux	1 (10)
Dry mouth	1 (10)
Loose stool	1 (10)
Increased appetite	1 (10)
Difficulty falling asleep	1 (10)
Limping with possible pain	1 (10)
Early morning wakening	1 (10)
Decreased fluid intake	1 (10)
Distractibility	1 (10)
Constipation	1 (10)
Increased frustration	1 (10)
Oppositional	1 (10)
Upper respiratory tract infection	1 (10)
Agitation	1 (10)

Results: Efficacy

Abstract

Background: The Clinical Global Impression-Severity (CGI-S) and CGI-Improvement (CGI-I) scales are widely accepted tools that measure overall disease severity and change, synthesizing the clinician's impression of the global state of an individual. Frequently employed in clinical trials for neuropsychiatric disorders, the CGI scales are typically used in conjunction with disease-specific rating scales. When no disease-specific rating scale is available, the CGI scales can be adapted to reflect the specific symptom domains that are relevant to the disorder. Angelman syndrome (AS) is a rare, clinically heterogeneous condition for which there is no disease-specific rating scale. This paper describes efforts to develop standardized, adapted CGI scales specific to AS for use in clinical trials.

Methods: In order to develop adapted CGI scales specific to AS, we (1) reviewed literature and interviewed caregivers and clinicians to determine the most impactful symptoms, (2) engaged expert panels to define and

Results: The resulting CGI-S/I-AS scales capture six critical domains (behavior, gross and fine motor function, expressive and receptive communication, and sleep) defined by caregivers and expert clinicians as the most challenging for patients with AS and their families.

Results: The resulting CGI-S/I-AS scales capture six critical domains (behavior, gross and fine motor function, expressive and receptive communication, and sleep) defined by caregivers and expert clinicians as the most challenging for patients with AS and their families.

Conclusions: Rigorous training and careful calibration for clinicians will allow the CGI-S/-I-AS scales to be reliable in the context of randomized controlled trials. The CGI-S/-I-AS scales are being utilized in a Phase 3 trial of gaboxadol for the treatment of AS.

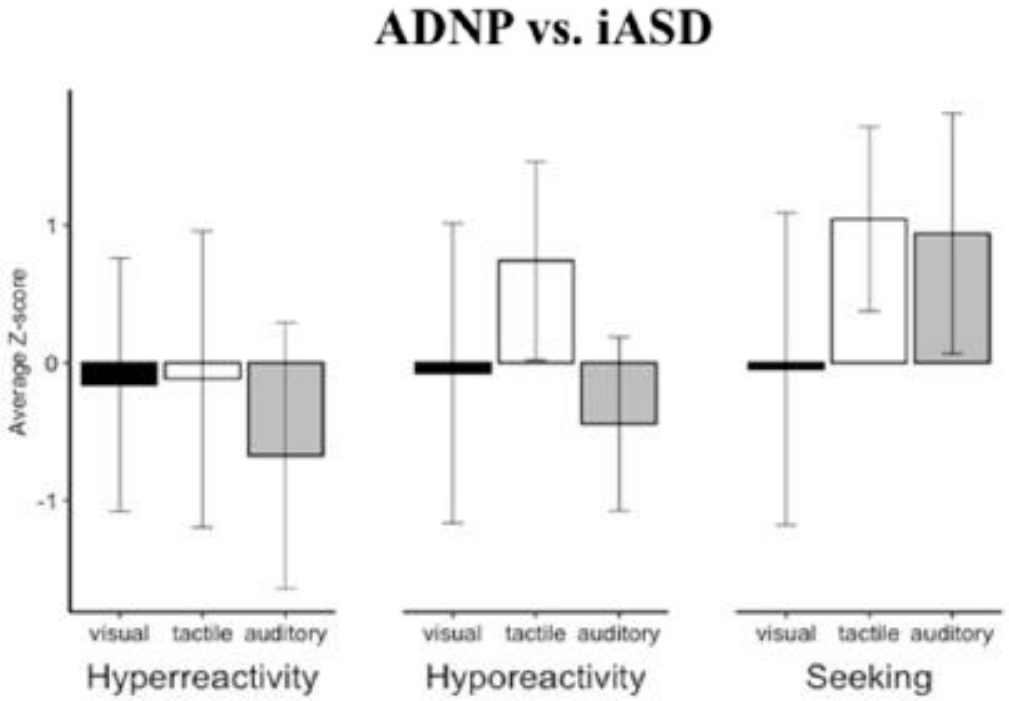
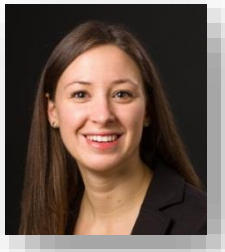
Foss-Feig [1,2], Silvia De Rubeis [1,2,3,8], Teresa Tavassoli [9], Joseph D. Buxbaum [1,2,3,8,10,11] and Alexander Kolevzon [1,2,3,12]



Computerized Eye Tracking

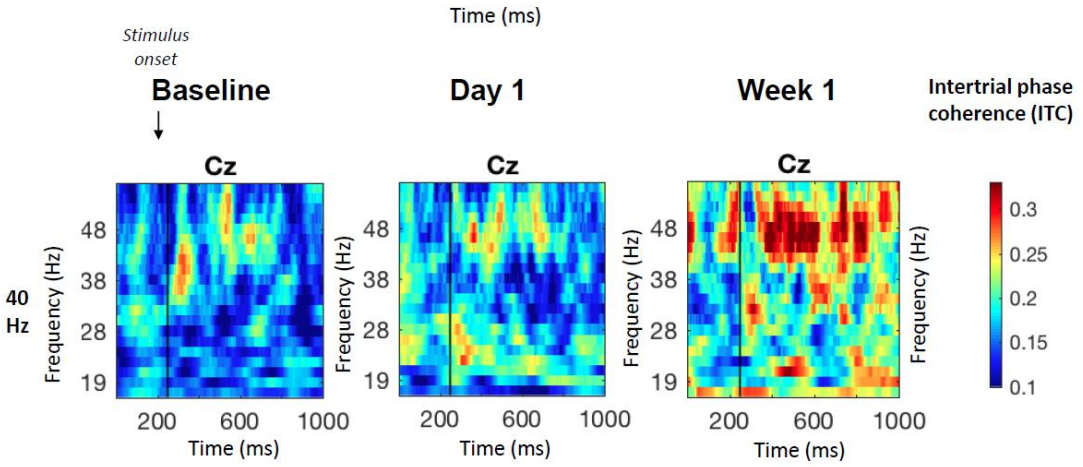
- The Gap Overlap task measures engagement and dis-engagement of visual attention to social (e.g., child faces) and non-social (e.g., objects like a ball) stimuli.
- The Joint Attention task measures ability to follow eye gaze of another person looking at objects versus a distractor.
- Results suggest this tool may be a useful marker of change in social attention with ketamine.

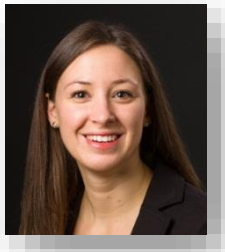


J. Foss-Feig, PhD

EEG Biomarkers: Auditory Steady State Response

- Participants hear a series of clicks at a stimulation rate of 40 Hz.
- Auditory Steady State Response (ASSR) is recorded with EEG nets where the coherence between trials of clicks is measured using time-frequency analysis and reflects synchrony between nerve cells.
- ASSR is considered a measure of the balance between excitatory (glutamatergic) and inhibitory (GABAergic) neural systems.
- Results suggest that ASSR may be a useful marker of change with ketamine and may also be associated with sensory symptoms.





J. Foss-Feig, PhD

Summary

- ADNP syndrome offers a unique opportunity to study a specific genetic cause of ASD in which the neuropathology is better understood and can more readily be targeted for treatment
- Studies still need to carefully phenotype and select for target symptom/s of interest
- Need improved clinical outcome assessments specific to ADNP syndrome
- Need to develop/validate biomarkers
- Eventually, treatments in ADNP syndrome may inform treatment development in subsets of people with ASD more broadly

Future Directions

- Design a placebo-controlled treatment trial using low-dose ketamine
- Likely switch to intramuscular administration (vs. intravenous) for better ease of use
- Treatment will consist of 8 doses over at least 4 weeks likely using a crossover design
- Obtain investigational new drug application (IND) from FDA to conduct research studies
- Select additional sites to reduce travel burden on families
